*Abstract* - The study was aimed at developing snacks (rockbuns biscuits and queen’s cake) from composite flour of *Dioscorea alata* (water yam) and defatted *Telfairia occidentalis* seeds (fluted pumpkin seeds) and to evaluate the snacks for acceptability. The study adopted an experimental design. *D.alata* tubers and *T. occidentalis* seeds were processed into flour using different methods. Rockbuns, biscuits and queen’s cake were produced from the composite flour. Chemical composition of these snacks were determined. The samples were also subjected to organoleptic analysis on (colour, texture, taste, flavour and General Acceptability). A nine – point hedonic scale was used. Twenty panelists were used for the evaluation. Data was analyzed using mean and analysis of variance (ANOVA). Supplementing defatted *T.occidentalis* seeds flour at 10%, 20% and 30% resulted in an increased in protein and Ash content of the snacks. For Rockbuns, protein content ranged from (5.09%) to (7.78%), for Biscuits, the protein content raged from (5.41%) to (6.82%), and for Queen’s cake, (5.58%) to (6.82%). Result of organoleptic evaluation revealed that, 100% wheat flour (control) was most preferred, followed by samples with 90%. *D.alata* and 10% *T.occidentalis* seeds flour for all the samples. It was concluded that *D.alata* and *T. occidentalis* seeds flour blends at 90:10 ratio could find useful application for snacks products for which wheat flour has been used.

**Keywords** – Analysis, Acceptability, Composite flour, Evaluation, Organoleptic.

**I. INTRODUCTION**

Protein malnutrition is a major public health problem in most developing world; diet in these parts are predominantly starchy, the major food crops being roots and tubers. In countries such as Nigeria, animal products representing high concentration and quality of protein are either unaffordable or too expensive thus, increasing the dependence on, tuber, roots and cereal crops. This has resulted in an inadequate intake of protein leading to various forms of malnutrition in both children and adult. It has been reported that in developing countries including Nigeria, malnutrition persists as a principal health problem among children below the age of five (UNICEF, 1996). Tuber and root crops are consumed in Nigeria in several forms. In most cases, they are milled into flour and used in preparing various items, (Fasasi, Adeyemi and Fagbenro, 2010). Roots and Tubers are often considered as an inferior food because they are low in protein, essential minerals and vitamins, therefore the need to find alternative sources of protein of good quality.

*Dioscorea alata* is a tuber crop widely cultivated in Nigeria, it is used in the production of various food items such as pounded yams, a replacement for maize in diets for laying hens, amala (popular darkish Nigeria food), snacks among others Adams, 2010). Snacks according to Anozie, China and Beleya, (2014) are small meals eaten between the main meals in order to maintain health, while satisfying appetite. In the same vein, Okpala and Okpala cited in Anozie et al. (2014), noted that, snacks are often smaller than the regular meals and are designed to be portable, quick and satisfying than prepared meals. Many snacks are low in nutritional value. However, in recent times, snack are being supplemented as to provide consumers with the much needed nutrients.

Snacks are mostly produced from wheat flour. However, Opkala and Okoli (2011) noted that, in many regions of the world, wheat flour is unavailable or uneconomical. Thus in such countries like Nigeria, they have to rely on importation of wheat flour to sustain the production of snacks or exclude wheat product from the diet. Studies revealed that, the demand for snacks and pastry product is on the increase and the cost of the products has become very expensive (Sanful and Darko, 2010). Thus, to sustain the consumption of snacks, and reduce the importation of wheat flour, there is therefore a need to source for alternative source of flour as substitute for wheat flour or partially replace wheat flour in the production of snacks. The replacement of wheat flour requires the development of an adequate substitute in terms of functionality, cost and availability. Attempts have been made to produce flour from other cereals apart from wheat as well as composite flour from different food categories.

Flour produced from either cereals, legumes and tubers only will have a nutritional value inferior to those produced from a combination of cereals legumes or tubers (Barber, Beleya, Eke and Owuno, 2010). In selecting the components to be used in composite flour blends, the material should be readily available culturally acceptable and provide an increased nutritional potential (Akobundu, Ubbanu and Ndupud, 1998). According to FAO (1995), composite flours produced from legumes have the advantage of improving overall nutrition. Therefore, composite flour produced from legumes and tubers will have high protein content and will also have high calorific value (Chinma, Ingbian and Akpapaunam, 2007). The production of composite flour from different food crops will result in flours that can be used as a replacement for wheat in the production of snacks. Awan, Rehman, Salim-
ur, Rehman, Ismail and Hashmi (1995) noted that, composite flours are also advantageous in the sense that, the inherent deficiency of essential amino acids such as lysine in wheat flour is supplemented from other food crops such as legume. Barber et al (2010) stated that, to improve the nutritional value of cereal-based diets, legumes should be used to fortify them. The nutrient content of legumes makes them natural complements to cereal-based diets. Legumes have also been recognized as the second most valuable plant source for human and animal nutrition (Sanni, Adebowale and Yusuf, 2006).

Legumes include soybean (Glycine max), cowpea (Vigna unguiculata), African Yambean (Sphenostylis stenocarpa), fluted pumpkin seed (Telfairia occidentalis) etc (Sanni et al, 2006). According to the authors, Telfairia occidentalis seed is one of the most important food legumes in Africa and south East Asia. It is the most widely grown legume and one of the cheapest sources of plant protein (Chido, 2007).

Studies have shown improvement in protein content of several cereal and tuber foods supplemented with legume such as bambara groundnuts/ sesame seeds and fluted pumpkin seeds (Giarni and Barber, 2004; Alobo 2001). Barber et al (2010) reported that addition of 50 percent cowpea to malted sorghum resulted in an increase in protein, ash, and crude fibre content of sorghum cowpea blends. Snacks have been produced from composite flours of tubers and cereals. Olapade and Ogunade (2014) produced crunchy snacks from potato and maize composite flour with high acceptability. Abayomi, Oresanya, Opeifa and Rasheed (2013) evaluated the quality of cookies produced from sweet potato and fermented soybean flour. Their findings revealed that cookies with 20% soybean substitution had the highest mean for overall acceptability and was nutritionally superior to the other samples. The findings of Abayomi et al (2013) buttress the fact that composite flours of tubers and legumes have a high nutritional quality. Thus enrichment of Dioscorea alata flour with Telfairia occidentalis seeds flour will improve the nutrient quality of the flour and products from the composite flour will have a high nutritional quality. However, there is no published work on the nutrient composition and other characteristics of snack (Rockbuns, Biscuits and Queen’s cake) produced from composite flour of Dioscorea alata and Telfairia occidentalis seeds flour.

II. PURPOSE OF THE STUDY

The purpose of this research was to develop snacks (Rockbuns, Biscuits and Queen’s cake) from composite flour of Dioscorea alata tubers and defatted Telfairia occidentalis seeds and to test the snacks for acceptability. Specifically the study determined:

1. The chemical composition: moisture, ash, fat, protein, carbohydrate and crude fibre of the products
2. Determined the acceptability of the products based on colour, texture, taste, flavour and general acceptability

III. MATERIALS AND METHODS

Materials

Freshly harvested T. occidentalis fruits were obtained from a local farm in Ahoada East Local Government Area of Rivers State. D. alata tubers were purchased from Mile One Market in Port Harcourt. Sugar, shortening (Simas margarine), eggs, salt, nutmeg, baking powder, milk, vanilla essence, etc were bought from mile three market in Port Harcourt. All equipment, reagents and chemical used were of analytical grade.

Production of Dioscorea Alata Flour

D. alata tubers were washed in running tap water and peeled manually using a stainless steel knife. The tubers were then sliced and re-washed. The sliced D. alata were soaked in tap water containing sodium meta-bisulphite in order to prevent any browning reaction and were blanched in hot water at temperature of 100°C for a minute. The blanched D. alata were oven dried at 60°C for 18 hours in a hot-air fan oven (model QUB 305010G Gallenkamp UK), milled using a commercial mill and screened through a 500mm mesh size British standard sieve (model BS 410 Endecott Ltd London, UK) to obtain a uniform fine flour and stored in an airtight plastic container at room temperature (37°C) until used.

Production of Telfairia Occidentalis Seed Flour

T. occidentalis fruits were cut open to obtain the seeds. The seeds were separated from the pulp; seeds with intact coats were washed in running tap water. The seeds were then blanched and stored in an airtight plastic container at room temperature (37°C) until used.

Sample Formulation

Four samples were formulated for each of the products. 100 percent wheat flour was used as control for all the samples while, the other samples were produced from D.alata and T. occidentalis seeds flour using a ratio of 90:10, 0:20 and 70:30.

Production of rockbuns recipe

Ingredients Quantity

Flour 200g
Sugar 80g
Margarine 80g
Nutmeg 1 tsp
Back ing powder ½ tsp
Eggs 2
Milk 20ml
Water 20ml
Salt 0.3g

Copyright © 2016 IJAIR, All right reserved 656
Procedure for preparation of rockbuns
1. Sieve all dried ingredients
2. Rub in fat and flour
3. Add sugar
4. Beat egg with milk until mixture becomes foamy
5. Add mixture and water to form consistency that can hold its shape
6. Pile in a greased baking tray in rough heaps
7. Bake in a hot oven for 15 minutes
8. Allow to cool
9. Serve

Production of Biscuits Recipe

Ingredients | Quantity
---|---
Flour | 200g
Margarine | 80g
Sugar | 80g
Baking powder | ½ tsp
Milk | 20ml
Water | 20ml

Procedure for production of biscuits
1. Sieve all dried ingredients
2. Rub in fat and flour
3. Sir in the sugar
4. Add milk and sufficient water to form a stiff dough
5. Roll out thinly and prick with a fork
6. Cut with a biscuit cutter and place in a well greased baking tray
7. Bake in a moderately hot oven for 5-10 minutes
8. Allow to cool
9. Serve

Production of Queen’s Cake Recipe

Ingredients | Quantity
---|---
Flour | 200g
Sugar | 80g
Margarine | 80g
Baking powder | ½ tsp
Nutmeg | 1 tsp
Milk | 20 ml
Vanilla essence | ½ tsp

Procedure for the production of Queen’s cake
1. Sieve all dried ingredients
2. Cream fat and sugar in a bowl until soft and fluffy
3. Add beaten eggs in bits mixing vigorously in each addition to prevent curdling
4. Add sieved flour, baking powder, nutmeg
5. Add milk and vanilla essence to get a high dropping consistency
6. Pile in a well greased petty cake pans
7. Bake in moderately hot oven for 15-20 minutes
8. Allow to cool and remove from the pans
9. Serve

Chemical Analysis

The proximate composition of the sample was determined according to standard AOAC methods (AOAC, 1995). Crude protein was determined by Kjeldahl method. A factor of 6.25 was used to convert N2 to protein. Fat was determined by soxhlet extraction method using petroleum spirit as solvent while, carbohydrate was determined by difference. Ash was determined by atomic absorption spectrophotometry (UV = Visible 754, China). Crude fibre was determined according to AOAC 1995.

Sensory Evaluation

Coded samples of rockbuns biscuits and queen’s cake were placed on white saucers and presented to a twenty members panel consisting of staff and students of Federal College of education (Technical) Omoku. The panelists were selected on the basis of age not less than 18 years and familiarity with the products. An evaluation sheet designed on a nine point hedonic scale was used for the evaluation of the samples with one (1) representing dislike extremely and nine (9) like extremely (Iwe, 2002). The attributes assessed were colour, texture, taste, flavour and general acceptability. The panelists were instructed to rate colour before tasting each product. Water was supplied to the panelists for rinsing their mouth in between tasting. Analysis of variance (ANOVA) was performed on the data collected to determine differences while Duncan Multiple Range Test (DMRT) was used to detect significant difference among the means at a level of 0.05.

Table 6 shows the mean sensory score for Queen’s cake prepared from 100 percent wheat flour (control) and composite flour of \( D.alata \) and \( T.occidentalis \) seed flour. For all the attributes evaluated sample QCA had the highest rating followed by same QCB, while QCD was rated least.

**V. DISCUSSION**

Results from the chemical composition of rockbuns, biscuits and queen’s cake shows that the protein content of the samples produced from the composite flour of \( D.alata \) and \( T.occidentalis \) had higher protein content than the control (100% wheat flour). This could be due to the significant quantity of protein in \( Telfaria occidentalis \) seeds flour as noted by (Anozie; et al, 2014; Giami, Achinewhu and Ibaakee, 2005; hamed, El-Hassan, Eltayeb and Babiker, 2008). The same observation was reported by Abayomi, Oresanya, Opeifa and Rasheed (2013), that cookies produced from blends of sheet potato flour and soybean flour had higher protein content. Anozie et al (2014), reported that composite flour produced from legumes and tubers have high protein content and calorific value. There was an increase in ash content of all the samples produced from the composite flour of \( D.alata \) and \( T.occidentalis \) seed flour.

This result is in accordance with the report of Agu and Aluyah cited in Anozie et al, (2014) high mineral content in maize soybean fluted pumpkin seeds blends with ash content of 2%. Increased ash composite flour of wheat and African yam been was also reported by Idowu, 2014. Decrease in the carbohydrate content of the samples produced from the composite flour of \( D.alata \) and \( T.occidentalis \) seed flour agrees with the report of Ibaakee (2008) that, carbohydrate content of products from composite flour decreased with an increase in addition of \( T.occidentalis \) seed flour, \( T.occidentalis \) seed according to Ibaakee is known to contain low carbohydrate than wheat flour. However there was an increase in carbohydrate content of the control samples. Results of the sensory evaluation of colour shows that, the control RBA, RSA and QCA were rated highest followed by sample RBB, BSB and QCB with 10% supplementation.

Appearance of food is usually the first sign of acceptability and edibility of a food product (Anozie et al, 2014). The texture of all the samples produced from 100% wheat flour (control) had higher scores than the samples produced from the composite flour of \( D.alata \) and \( T.occidentalis \) seed flour. Chinma, Igbabul and Omotayo (2012) reported a higher texture score for 100% wheat flour cookies which was attributed to the presence of gluten in wheat flour. Texture of food according to Iwe and Egwuekwu, (2010) depends a lot on the starch content. The mean sensory score for taste showed that sample RBD, BSD and QCD with 30% \( T.occidentalis \) seeds flour were rated lowest. The quality attributes decreased with increase in the level of \( T.occidentalis \) seeds flour addition with respect to taste and flavour. Anozie et al (2014) observed that cut of chinchin and strips of chin chin containing more than 10% \( T.occidentalis \) seeds flour have an after taste and this affected their rating. For general acceptability, sample RBA, BSA and QCA were most preferred, followed by samples RBB, BSB and QCB with 10% level of supplement of \( T.occidentalis \) seeds flour.

**VI. CONCLUSION**

The chemical analysis of snacks made from composite flour of \( D.alata \) and \( T.occidentalis \) seeds flours showed significant increase in protein and Ash content, and this indicates a high nutritional value with respect to protein and mineral content. The statistical analysis of the sensory evaluation of Rockbuns, Biscuits and Queen’s cake with 10% supplementation of \( T.occidentalis \) seeds flour were most preferred after the control samples. This revealed that 10% \( T.occidentalis \) seeds flour can be added to flours for snacks production to improve its nutritional value and eating quality. This without skepticism will contribute to reducing the problem of protein-energy malnutrition. Use of composite flour for snacks making will add value to these local crops and reduce over dependence on wheat flour thereby saving the country’s foreign exchange earnings.

**VII. RECOMMENDATION**

Based on the result of this research, it is therefore recommended that;

1. \( D.alata \) and \( T.occidentalis \) seeds flour blends can find useful application for snacks products for which wheat flour has been used.
2. Products developed from a blend of \( D.alata \) and \( T.occidentalis \) seeds flour can be very useful snacks product in respect to nutritional value.
3. Popularizing the use of these flour blends for such products for which wheat flour is used, will go along way to reduce the country’s dependency on wheat flour hereby saving scarce foreign exchange.
4. Substituting up to 10% level of \( T.occidentalis \) seeds flour in product development using \( D.alata \) and other root and tuber crops, including cereals will improve its nutritional value.

AUTHOR’S PROFILE

China Mercy Ameke Hamilton was born 18th January 1972, in Nigerin from Rivers state. Currently a Lecturer with Federal College of Education Technical Omoku, in Home Economics Department. She obtained her M.Sc in Home Management in 2014 and currently pursuing a Ph.D. in the same area, holds a B.Ed., NCE in Home Economics from rivers state college of education Port Harcourt and FCE (T) Omoku respectively. She holds some professional certificates such as, Teacher’s Registration Council 2006, certificate of merit on family life and emerging health issues (FLEEH)2010 etc.

She served as exam officer, member protect review committee seminar coordinator, had taught in some secondary schools in rivers state as a classroom teacher.

She has some publications to her credits among which are:

Dr. Priscilla N. Ezema was born In Nsukka Nigeria in the year 1957. She is an Associate Professor of Home Economics. She obtained her Ph.D (Home Economics), 2011, M.Ed (Home Economics), 2005, M.EdScience Education, 1988 and B.Sc (Hons) Home Economics, 1983 all from University of Nigeria Nsukka. Priscilla is currently teaching in the department of Home Economics, Michael Okpara University of Agriculture, Umudike, Nigeria. Her fields of interest are clothing and textiles, entrepreneurship, food and nutrition and teacher education. She transferred her service from Federal College of Education, Eha-Amufu, Nigeria where she served as member of the College Governing Council, Dean, School of Vocational Education and Head of department of Home Economics. She is a member of various professional bodies among which are IFHE worldwide and Regional, Home Economics Research Association of Nigeria, Home Economics Council of Nigeria etc. She has some publications in both international and national journals, a textbook and many chapter contributions.
